# Here's HUEY!

... super calculator for the 6502

hat hobbyist wouldn't like to have available the calculating power of FORTRAN in his system? Here is HUEY, written for the 6502 microprocessor, which does arithmetic with precision better than an IBM 360/370 or Univac 1108, unless they pull a dirty trick and switch to double-precision mode. What's more, HUEY (please don't call him Hewlett) operates from your ASCII keyboard like a calculator; will output through your routines to a TV screen or Teletype; is preprogrammed to do trig functions, natural and common logs,

exponential functions and other goodies; and is programmable for many other functions (financial, accounting, mathematics, engineering, etc.) you would like to call at the press of a single key. Further, the routines can be called as subroutines by your own programs if you need the precision or the functions HUEY provides.

All this is contained in 2.5K of memory, with optional expansion to 3K by addition of your own functions.

The complete hexadecimal listing of the program is given

in Table 1. The basic program occupies addresses 1000 through 19FF, but you will wish to reserve 1AOO through 1BFF if you intend to add other functions. The program uses page zero extensively for arithmetic registers and memory registers, and you should avoid using addresses 0020 through 009F for your video routines or other programs. The program itself, sets all these locations at the values it wants, so there is no extensive entry into page zero required before the program can be used. Arithmetic overflow, division by zero, logs of negative numbers and other no-nos divert the program to software breaks. If you set your IRQ vector to go to address 1164, a break will give you an error code on your display. This code, shown in Table 2, is simply the address of the break, plus two. The error code will be followed by a string of zeros on the next line.

#### **Entering the Program**

For ease of entry, all of the basic user options in the program are contained in the first few bytes of the listing. Program A will allow you to select the options and provide entry to your input/output routines. Although the accesses to your input and output routines appear to be jumps, in all cases they originate deep within the inner workings of the program as jumps to subroutines. So, when your input or output routine is through doing its thing, however long it takes, it must end with op code 60 (return from subroutine). Just to be safe, set Y to zero just before returning, although I thought this kind of bug was exterminated prior to printing.

The request by the program to output a character is, in all cases, preceded by instructions within the program to place the ASCII character in the accumulator of the microprocessor. Similarly, when it asks for an input, it expects its ASCII equivalent to be in the accumulator. Your routines should restore the stack pointer, since the stack has what your mail should have on the upper left corner namely, the return address. If you have Tiny BASIC, identical input/output routines can be used.

#### Press Go, Start, or Whatever

Your initialization routines can do whatever you like (clear the TV screen, set the IRQ vector or turn on the coffee), but when they are finished, there should be a

1006	4C,xx,yy	A jump to your input routine.
	, ,,,,	xx is ADL, yy is ADH.
1009	4C,xx,yy	A jump to your output routine.
100C	5C	Choice of default character.
100D	2A	Choice of exponent symbol.
100E	09	Number of digits entered or
		displayed. Enter number
		between 02 and OD.
100F	08	Choice of back space code.
1010	ÖÖ	Expansion.
1011	01	Delay time for typewriter
		carriage return. Use 01 for
		shortest time. FF for longest.
		FF gives 0.3 sec for 1 MHz clock.
1012	1B	Character used to TAB to
		exponent.
1013	00	Expansion.
		•
		Program A.

Code	Description
14F9	Overflow in Exponent calculation.
157D	Square root of negative number.
15C7	Natural log of negative number or zero.
16E6	Floating point overflow (number too large).
176F	Division by zero.

Table 3. Page zero assignments.

ADDRESS	DATA	FUNCTION
1526	83	Sets Z key to call address 1B80
1B80	EA	Recall pi
1B81	80	Divide
1B82	12	Move stack down after arithmetic
1B83	32	Set up to call string as subroutine
1B84	EO	Square root string
1B85	00	End
	P	rogram B.

jump to HUEY's point of COLD START at address 1000. HUEY will set the stack the way he likes, clear his registers in page zero, output a line of zeroes and output a colon, which is his way of telling you that he's waiting for you to press a key. The screen or typewriter should look like this:

0.00000000\* 00

By the way, to keep the program short, I had to limit HUEY's vocabulary to scientific notation. That means all entries should have the decimal point after the first digit, and the number that follows the star is the

power of ten that multiplies the first part.

OK, let us determine what 1 divided by 3 is, and we will then go on to more glamorous experiments. Press 1; press P (to enter the *positive* number you have just pressed into the X-register). Your display will now show:

:1.P 1.00000000\* 00

Note that HUEY has forced you to use scientific notation by typing a decimal point immediately following your 1, and has displayed the contents of the X-register. HUEY displays the X-register after every function, just like your \$9.95 pocket calculator (at this point you may ask why you paid 100 times this amount for your system, but read on!).

Next, press 3, and then P. The display should now show 3 in our notation. Now, let us divert for one moment to check our work. Let's press K to see what the HUEY stack of four registers contains. The display should be as follows, except that the X, Y, Z and T are not actually displayed.

:K T 0.00000000\*00 Z 0.00000000\*00 Y 1.00000000\*00 X 3.00000000\*

means 0.3333333333 in ordinary terms, since the minus 01 exponent indicates the decimal point moves one place to the left.

Let's re-examine the stack at this point by pressing K. Note that both dividend and divisor are lost in the arithmetic process, and that Z has moved to Y; in the process T remains unchanged, but is duplicated in Z.

:K 0.00000000\* 00 0.00000000\* 00 0.00000000\* 00 3.333333333\*-01

These features of the stack may or may not have anything to do with HUEY's name. The stack operations, by the way, are outlined in Fig. 1. For clarity of display on a TV screen or typewriter, the ROLL operation has been reversed from that used by hand calculators of similar name. You may load up to four numbers into the stack and then perform your arithmetic functions by combinations of rolls, X/Y exchanges, stores in memory, recalls, interspersed with arithmetic commands; and any time you have lost track of what is in the stack, just press K. All arithmetic operations are done on X and Y, without losing Z and T. There is no need to clear the stack registers; just enter new numbers, and the old ones disappear off the top.

Want to enter an exponent without entering all those zeros? Press ESC (or whatever ASCII key you have selected for this function at 1012) and HUEY will fill in the zeros for you. Negative numbers? Just press N instead of P to enter your number as a negative value. Negative exponents? Subtract your desired negative value from 100 and enter the result. For example, if you want to enter -09 as an exponent, enter 91. HUEY will echo the value he read so you can be sure. In this case, the echoed exponent will read -09. Back

X-register 0020-0026	E-register 0027-002D							
Y-register 0030-0036	Memory M1 0037-003D	etc.

space works on both the number and the exponent, if you make a mistake, or you can press @ to clear your entry.

#### Sample Calculation

Suppose you have the area of a circle and want the radius. Simply use the sequence in Example 1.

If you have many values of radius you wish to calculate, you can preprogram, say, the Z key to do the entire operation with one keystroke, after the area is entered, as shown in Program B.

With these modifications to the program, you simply press number keys for the area, press P to enter as a positive number, and then your magic key Z. Repeat for as many calculations as you like. This simple illustration probably does not warrant preprogramming, but it illustrates the power of the system for more complicated calculations.

If you reset your system for any reason, you can reenter HUEY at address 1003 for WARM START, which will not destroy the contents of the arithmetic registers.

HUEY recognizes, as functions, ASCII entries 2A through 2F (which includes the arithmetic functions) and 3A through 5A (all the uppercase letters and a few punctuation marks). All other ASCII entries are rejected, excepting, of course, the numbers and the special back space and tab functions. Preprogrammed functions are listed in Table 5.

Unused keys can be used for other functions. I have

calculated such diverse things as compound interest, hyperbolic functions, 99-term power series and others by adding 12-60 byte programs to page 1A.

Numbers are limited in size to about 1.00000000\* 37.

#### The Inner Workings

The arithmetic operations occupying page 16 are a floating point package originally printed in Dr. Dobb's Journal, but the package has been modified to use 47-bit arithmetic instead of the original 23-bit. (IBM single precision is 24 bits and Univac is 27.) Our 47 bits gives a precision to arithmetic operations of about 13 equivalent significant figures in decimal. The algorithms for In, exp. sin, cos, tan and arctan can be counted on for eight-place accuracy, with the trig functions limited to the range 0-90 degrees or 0-pi/2 radians. Square root is performed with accuracy equivalent to the arithmetic operations.

The high precision is, of course, obtained at some sacrifice of speed, but this program is intended for the person who has some serious calculating to do, and not for the game-player who is satisfied with a number system allowing no fractions and having numbers limited to -32K to +32K.

The routines limiting the speed are the conversion of decimal to binary (page 14) and conversion of binary to decimal (page 13). This can be observed by the slowness of entry and display of very

The following functions are associated with number entry and stack manipulation:

- Enter as positive number into X Enter as negative number into X Clear entry (use before P or N pressed) Display stack contents
- Roll the stack up (X to Y, Y to Z, Z to T, T to X)

Exchange X and Y

The following operate on X and Y and leave the result in X, with the stack dropping down to fill in; T is duplicated in Z:

- X added to Y
- X subtracted from Y
- X multiplied by Y
- Y divided by X

The following operate on X, leaving the other stack registers unchanged (arctan does bomb it):

- Antilog X (base 10)
- Cos X (radians)
- Е Exponent (e raised to the X power)
- G Log X (base 10)
- Inverse of X (1/X) Natural logarithm of X
- Square root of X
- Q S Sin X (radians)
- T Tan X (radians)
- Arctan X

The following functions are associated with memory and, in the case of recalls, push the stack up one notch:

> Right Arrow Left Arrow

Store X in M

Recall M into X

Recall pi into X (3,141592654)

Recall e into X (2.718281828)

Recall log e into X (0.434294481)

Table 5. Preprogrammed functions.

KEY	ACTION ·
Number Keys	Area
P	Enter as positive numbe
U	Recall pi
1	Divide to get A/pi
Q	Take square root

Example 1.

large and very small numbers, e.g., 1.00000000\*-37.

#### Memory Registers

Although only one memory (M1) is preprogrammed for keyboard access, two other registers, M2 and M3, are used by the program to store intermediate results. In addition, the stack, which appears to the user to be four registers, is actually six registers X, Y, Z, T, U and V. The two extras are used to simplify restoring the contents of the four "visible" registers. Register E is used by the floating point package. All of these registers are 7-byte binary registers. All arithmetic is done in X, Y

and E, and their original contents are stored elsewhere if restoration is desired.

In addition, register D is a 16-byte register that holds a number formatted in decimal, and register B acts as a line buffer and scratchpad. Fig. 2 shows the register locations in page zero. You can set up other registers in page zero if necessary.

Constants, such as pi, 0, 1 and SQRT2, are squeezed into available space throughout the program. Each constant requires seven bytes, and is in binary (hex) form. Other constants you may need, such as the tax rate on incomes over \$150,000, can be stored anywhere in your memory, and can be accessed by way of empty slots in the

of the string. In turn, each microinstruction refers to a subroutine call instruction, a recall memory instruction or a store instruction. If bit 7 of the microinstruction is 1, a memory register is recalled to X. If bit 0 is a 1, then X is stored in a memory register. Otherwise, the microinstruction is decoded as a subroutine call. In all cases, the middle bits (1-6) of the micro refer to the address table occupying the first half of page 12, where the address of the subroutine or memory is picked up. After the current micro is executed, the program picks up the next, until it reaches 00. After the execution of a string of microinstructions, a common output string (located at

method of assembly of this program, that is, completely by hand, anyone wishing to reassemble to another memory location should work in whole pages, since some portions must stay in the same relative position on the page. Reassembly to start at address 4000, say, is relatively easy, but reassem-

of microinstructions at address 1A80. At 1514, the H position in the table, enter 82. This 82 is derived from 80, the ADL of the string address, plus 2, the page offset from the base page 18. Now, enter a suitable string of microinstructions such as in Program C to solve your equation.

1A80	32	Set up to call a string as subroutin
1A81	BO	Call exponent string to get e**X
1A82	D4	Enter (make a duplicate copy in Y
1A83	32	Set up to call string as subroutine
1A84	48	Call invert string to get e**-X
1A85	04	Subtract
1A86	12	Move stack down after arithmetic
1A87	DC	Recall number 2
1A88	08	Divide
1A89	12	Move stack down after arithmetic
1A8A	00	End
		Program C.

Table 4. Preprogrammed constants.

address table. The location and hex values of the preprogrammed constants are shown in Table 4.

## What Happens When You Press a Key?

When a function key is pressed, the ASCII value is used to look up a coded address in the table starting at 1500. The coded address refers to every fourth address in pages 18, 19, 1A and 1B. I have preprogrammed functions in the first two of these pages, leaving pages 1A and 1B for your own functions. At selected addresses in pages 18 and 19 are strings of microinstructions, each string ending in 00 to signal the end

1808) is called by the mainline program. This exit string recalls a rounding constant a little bigger than 1, multiplies by X, converts the product to decimal, outputs the scientific format and restores the original contents of the stack. Note that rounding is applied only to the number being displayed and not to any binary registers, so that accuracy is maintained. For the purist, rounding can be easily disabled, but I hate to decode a string of nines!

A common entrance string is called by the mainline program, but it is not required at present and is disabled by the 00 at address 1800.

Because of the unique

bly to start at address 4080 would be quite a chore.

### A Sophisticated Example

When you have seen what the basic program will do, you may wish to calculate other functions. Let's say you want to preprogram for sinh(X), obtained by using the equation in Example 2.

$$sinh(X) = (e^{**}X - e^{**}-X)/2$$

Example 2.

Suppose you wish to use the H key for this function, and you wish to enter the string

With this short string, you can get sinh(X) each time the H key is pressed, or whenever the string is called by another string. Strings can be debugged by replacing any micro with 00 to stop the action at that point, and then pressing K to examine the stack.

A complete manual giving the details of this system, and including a documented listing of the program, is available from The Bit Stop, P.O. Box 973, Mobile AL 36601, for \$20 postpaid. Tapes are also available.

Encoding by use of microinstructions makes for a memory-efficient system, since each can call a machinelanguage subroutine using only one byte. Further, these microinstructions can set up loops to repeat a string as many times as desired, and can even call other complete strings as subroutines. All these features are illustrated in the arctan routine, which is about 60 bytes long, but results in calling some 200 machine-language subroutines before execution is complete.

My thanks go to Felton Mitchell, who got me off my can to write this, and who very kindly dumped off the hard copy.
